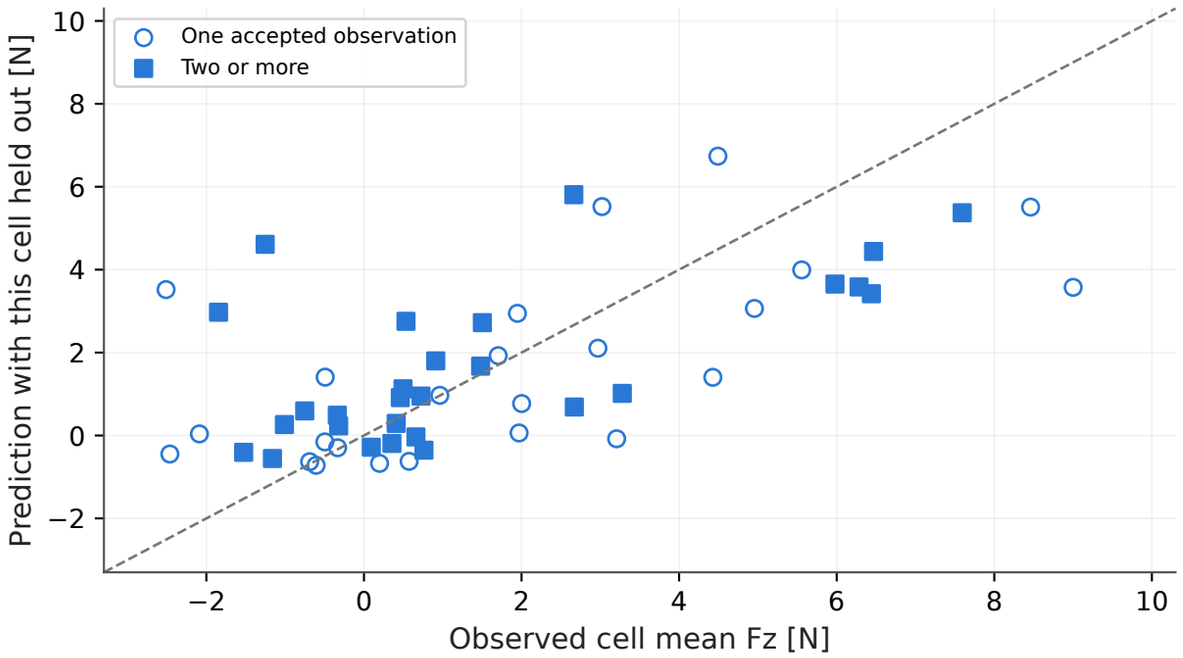
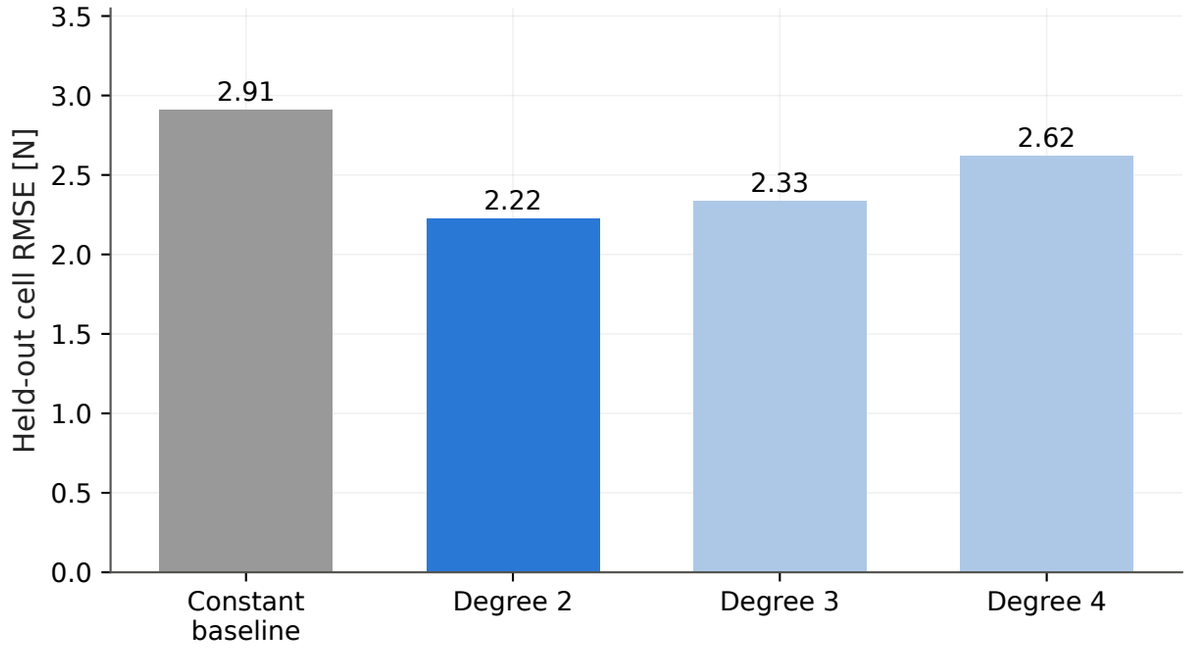
Audit of the conditional polynomial fit

The regression estimates a mean among trials that reached normal loading. It does not fit the full first-failure envelope.
24 / 52 fitted cells have only one accepted observation; crosses in the main figure are failures during drag or lateral loading.

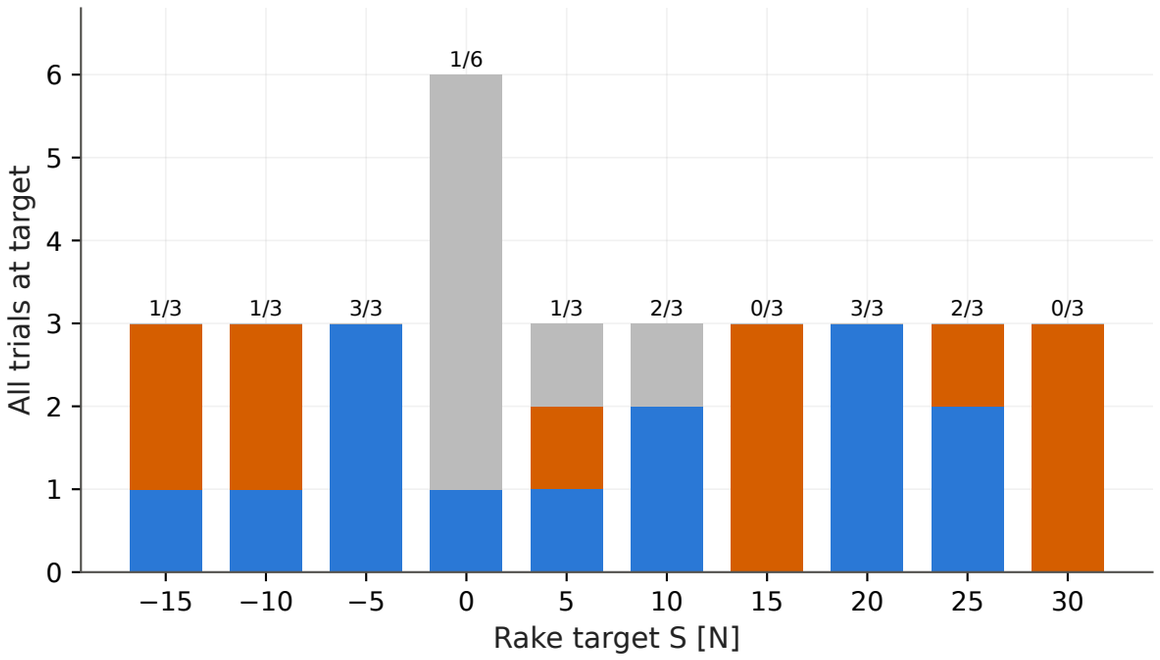
(a) Leave-one-cell-out RMSE = 2.22 N



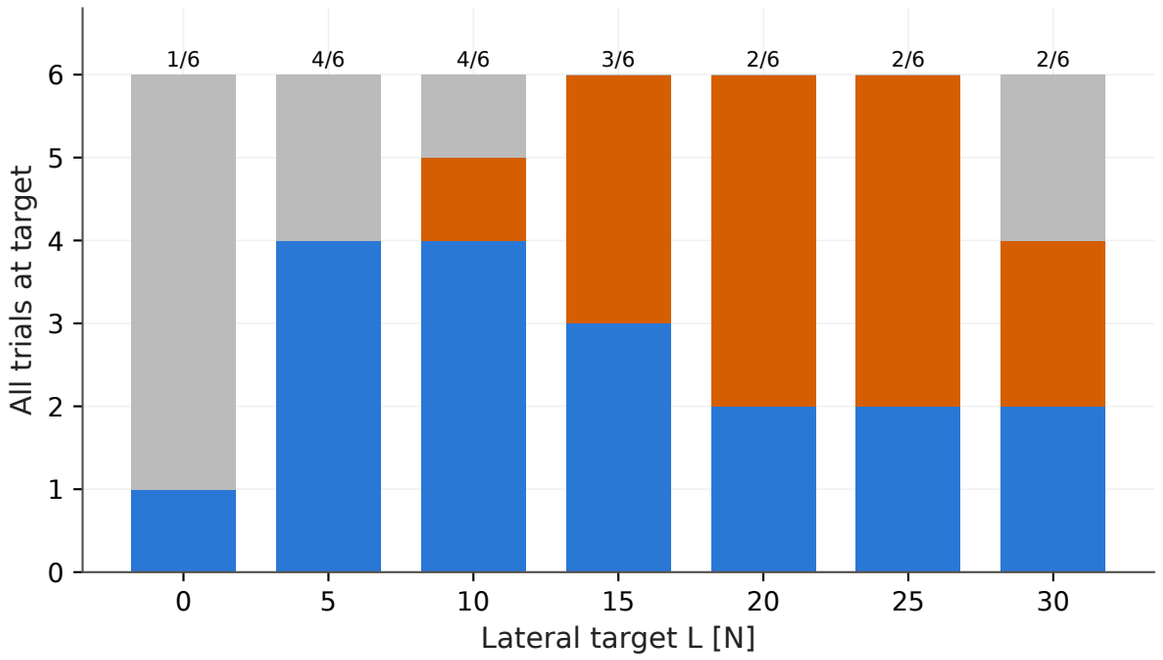
(b) Lowest candidate error is not physical validation



(c) L = 0: which repeats enter the curve?



(d) S = 0: which repeats enter the curve?



Accepted normal onset Slip before normal ramp Other / onset under review
